Abstract A list of Korean spiders was revised, including 46 families 225 genera 622 species which were reported by December 1999. Of these 61 added species and 37 altered scientific names were supplemented, and 3 species, which have been reported since June 1994, were newly synonymized. The spider fauna of Korea is composed of 12 Cosmopolitan, 34 Holarctic, 66 Palearctic and 136 Korean endemic species. The spider fauna of Korea has much more similarity with Japanese spider fauna than with those of other countries.

INTRODUCTION

The fauna list of spiders, which established at different scales, in the whole countries or smaller regions such as mountains and agricultural sites, serves the preservation of global and local biodiversity. Fauna lists are inventories, which not only help to establish patterns of diversity, but also serve as raw material for more detailed ecological studies (Samu and Szinetár, 1999).

Up to date, the lists of Korean spiders have been reported by Paik and Kim (1956), Paik (1967, 1971, 1978), Namkung (1976), Paik and Kim (1985, 1994), Kim (1991, 1997, 1998), and Im (1996, 1997). Since there have been confusions on the Korean spider fauna caused by additions of many species, alteration of a taxonomic system, typographical errors, misunderstanding and doubts of identification in the last lists and publications, all the lists and publications on Korean spiders were reviewed and a new list of Korean spiders was developed. All the papers reporting spiders from Korea and other countries by December 1999 were reviewed. Some species which had too simple faunistic list or ecological remarks were excluded from the new list. The taxonomic system of this paper was based on Paik and Kim (1994). Also, a recent taxonomic system which was proved to be valid on Korean spiders was accepted (Platnick, 1997). Some Korean species name of spiders, which were not proper or could cause confusion because of their discordance with genus name, were replaced by new Korean names with indication of "replaced name (改稱)" and "new name (新稱)" in parenthesis. Also, in our list, Korean species name, which have

two vernacular names, was adopted based on priority of the publication date. In addition, newly recorded genera formed by some species which were transferred to other genera were given by new Korean names. Among references referring added species and alteration or revision of scientific name, only the latest reports from Korea and other countries were considered with a hyphen below the scientific name in this paper. Question Mark in the parenthesis with Korea in distribution of some spiders means uncertainty of their distributions and identifications. Astric mark on the shoulder species number means newly recorded species from Korea and double astric mark means altered scientific name since June 1994.

From the review of all the papers reported spiders from Korea up to December 1999, the new list of Korean spiders in this paper included 46 families 225 genera 622 species (Table 1). Two species, *Coelotes jilensis* Song *et al.*, 1993 (Kim, 1998c : 28) belonging to Agelenidae and *Sitticus sinensis* Schenkel, 1963 (Kim, 1998c : 45) belonging to Salticidae which were reported from Chinese part of Mt. Baikdu named Mt. Jangbaik, were excluded from the new list because they have not been reported from Korea, although they are listed in the recent list of Korean spiders (Kim, 1998). Also, *Alopecosa striatipes* (C. L. Koch, 1837) and *Pardosa atropos* (L. Koch, 1878) belonging to Lycosidae are deleted because their existence and record from Korea are unreliable.

Atypus donggukensis, *Achaearanea ungilensis* and *Plexippoides joopili*, which have been reported since June 1994, were newly synonymized with an equal sign under scientific name. *A. donggukensis* is consistent with *A. coreanus* in its external feature, epigynum and structure of genitalia of female, and its type locality. *A. ungilensis* is consistent with *A. kompirensis* in palpal organ of male and *A. ungilensis* only showed color and pattern variation of *A. kompirensis*'s. *P. joopili* is consistent with *P. regius* in epigynum and structure of genitalia of female.

From the zoogeographical distribution, spider fauna of Korea was found to be composed of 12 Cosmopolitan, 34 Holarctic, 66 Palearctic, 136 Korean endemic, 1 Cosmotropical, 1 Holarctic and Pacific, and 2 Pantropical species. The spider fauna of Korea, therefore, is under strong influence of northern species. Because there are 410 common species at the amount of 66.0% between Korea and Japan, the spider fauna of Korea has much more similarity with Japanese spider fauna than with those of other countries (Table 2).
